Preface

Algorithms that process large data sets have to take into account that the cost of memory accesses depends on where the accessed data is stored. Traditional algorithm design is based on the von Neumann model which assumes uniform memory access costs. Actual machines increasingly deviate from this model. While waiting for a memory access, modern microprocessors can execute 1000 additions of registers. For hard disk accesses this factor can reach seven orders of magnitude. The 16 chapters of this volume introduce and survey algorithmic techniques used to achieve high performance on memory hierarchies. The focus is on methods that are interesting both from a practical and from a theoretical point of view.

This volume is the result of a GI-Dagstuhl Research Seminar. The Gesellschaft für Informatik (GI) has organized such seminars since 1997. They can be described as “self-taught” summer schools where graduate students in cooperation with a few more experienced researchers have an opportunity to acquire knowledge about a current topic of computer science. The seminar was organized as Dagstuhl Seminar 02112 from March 10, 2002 to March 14, 2002 in the International Conference and Research Center for Computer Science at Schloss Dagstuhl.

Chapter 1 gives a more detailed motivation for the importance of algorithm design for memory hierarchies and introduces the models used in this volume. Interestingly, the simplest model variant — two levels of memory with a single processor — is sufficient for most algorithms in this book. Chapters 1–7 represent much of the algorithmic core of external memory algorithms and almost exclusively rely on this simple model. Among these, Chaps. 1–3 lay the foundations by describing techniques used in more specific applications. Rasmus Pagh discusses data structures like search trees, hash tables, and priority queues in Chap. 2. Anil Maheshwari and Norbert Zeh explain generic algorithmic approaches in Chap. 3. Many of these techniques such as time-forward processing, Euler tours, or list ranking can be formulated in terms of graph theoretic concepts. Together with Chaps. 4 and 5 this offers a comprehensive review of external graph algorithms. Irit Katriel and Ulrich Meyer discuss fundamental algorithms for graph traversal, shortest paths, and spanning trees that work for many types of graphs. Since even simple graph problems can be difficult to solve in external memory, it
makes sense to look for better algorithms for frequently occurring special types of graphs. Laura Toma and Norbert Zeh present a number of astonishing techniques that work well for planar graphs and graphs with bounded tree width.

In Chap. 6 Christian Breimann and Jan Vahrenhold give a comprehensive overview of algorithms and data structures handling geometric objects like points and lines — an area that is at least as rich as graph algorithms. A third area of again quite different algorithmic techniques are string problems discussed by Juha Kärkäinen and Srinivasa Rao in Chap. 7.

Chapters 8–10 then turn to more detailed models with particular emphasis on the complications introduced by hardware caches. Beyond this common motivation, these chapters are quite diverse. Naida Rahman uses sorting as an example for these issues in Chap. 8 and puts particular emphasis on the often neglected issue of TLB misses. Piyush Kumar introduces cache-oblivious algorithms in Chap. 9 that promise to grasp multilevel hierarchies within a very simple model. Markus Kowarschik and Christian Weiβ give a practical introduction into cache-efficient programs using numerical algorithms as an example. Numerical applications are particularly important because they allow significant instruction-level parallelism so that slow memory accesses can dramatically slow down processing.

Stefan Edelkamp introduces an application area of very different character in Chap. 11. In artificial intelligence, search programs have to handle huge state spaces that require sophisticated techniques for representing and traversing them.

Chapters 12–14 give a system-oriented view of advanced memory hierarchies. On the lowest level we have storage networks connecting a large number of inhomogeneous disks. Kay Salzwedel discusses this area with particular
emphasis on the aspect of inhomogeneity. File systems give a more abstract
view of these devices on the operating system level. Florin Isaila explains the
organization of modern file systems in Chap. 13. An even higher level view is
offered by relational database systems. Josep Larriba-Pey explains their or-
ganization in Chap. 14. Both in file systems and databases, basic algorithmic
techniques like sorting and search trees turn out to be relevant.

Finally, Chaps. 15 and 16 give a glimpse on memory hierarchies with
multiple processors. Massimo Coppola and Martin Schmollinger introduce
abstract and concrete programming models like BSP and MPI in Chap. 15.
Dani Jimenez, Josep-L. Larriba, and Juan J. Navarro present a concrete case
study of sorting algorithms on shared memory machines in Chap. 16. He
studies programming techniques that avoid pitfalls like true and false sharing
of cache contents.

Most chapters in this volume have partly tutorial character and are partly
more dense overviews. At a minimum Chaps. 1, 2, 3, 4, 9, 10, 14, and 16
are tutorial chapters suitable for beginning graduate-level students. They are
sufficiently self-contained to be used for the core of a course on external mem-
ory algorithms. Augmented with the other chapters and additional papers it
should be possible to shape various advanced courses. Chapters 1–3 lay the
basis for the remaining chapters that are largely independent.

We are indebted to many people and institutions. We name a few in al-
phabetical order. Ulrik Brandes helped with sources from a tutorial volume
on graph drawing that was our model in several aspects. The International
Conference and Research Center for Computer Science in Dagstuhl provided
its affordable conference facilities and its unique atmosphere. Springer-Verlag,
and in particular Alfred Hofmann, made it possible to smoothly publish the
volume in the LNCS series. Kurt Mehlhorn’s group at MPI Informatik pro-
vided funding for several (also external) participants. Dorothea Wagner came
up with the idea for the seminar and advised us in many ways. This volume
was also partially supported by the Future and Emerging Technologies pro-
gramme of the EU under contract number IST-1999-14186 (ALCOM-FT).
