
Preface

This book is intended for molecular biologists who perform quantitative analyses on data emanating from their field and for the statisticians who work with molecular biologists and other biomedical researchers. There are many excellent textbooks that provide fundamental components for statistical training curricula. There are also many “by experts for experts” books in statistics and molecular biology which require in-depth knowledge in both subjects to be taken full advantage of. So far, no book in statistics has been published that provides the basic principles of proper statistical analyses and progresses to a more advanced statistics in response to rapidly developing technologies and methodologies in the field of molecular biology.

Responding to this situation, our book aims at bridging the gap between these two extremes. Molecular biologists will benefit from the progressive style of the book where basic statistical methods are introduced and gradually elevated to an intermediate level. Similarly, statisticians will benefit from learning the various biological data generated from the field of molecular biology, the types of questions of interest to molecular biologists, and the statistical approaches to analyzing the data. The statistical concepts and methods relevant to studies in molecular biology are presented in a simple and practical manner. Specifically, the book covers basic and intermediate statistics that are useful for classical and molecular biology settings and advanced statistical techniques that can be used to help solve problems commonly encountered in modern molecular biology studies, such as supervised and unsupervised learning, hidden Markov models, manipulation and analysis of data from high-throughput microarray and proteomic platform, and synthesis of these evidences. A tutorial-type format is used to maximize learning in some chapters. Advice from journal editors on peer-reviewed publication and some useful information on software implementation are also provided.

This book is recommended for use as supplementary material both inside and outside classrooms or as a self-learning guide for students, scientists, and researchers who deal with numeric data in molecular biology and related fields. Those who start as beginners, but desire to be at an intermediate level, will find this book especially useful in their learning pathway.

We want to thank John Walker (series editor), Patrick Marton, David Casey, and Anne Meagher, (editors at Springer and Humana) and Shanthy Jaganathan (Integra-India). The following persons provided useful advice and comments on selection of topics, referral to experts in each topic, and/or chapter reviews that we truly appreciate: Stephen Looney (a former editor of this book), Stan Young, Dmitri Zaykin, Douglas Hawkins, Wei Pan, Alexandre Almeida, John Ho, Rebecca Doerge, Paula Trushin, Kevin Morgan, Jason Osborne, Peter Westfall, Jenny Xiang, Ya-lin Chiu, Yolanda Barron, Huiibo Shao, Alvin Mushlin, and Ronald Fanta. Drs. Bang, Zhou, and Mazumdar were partially supported by Clinical Translational Science Center (CTSC) grant (UL1-RR024996).
