Abstract. In this paper, we synthesized single-walled carbon nanotubes (SWCNTs) using chemical vapor deposition (CVD) process in a furnace with three different heating regions. Ferritin nanoparticles were used as catalyst for the CNTs synthesis through carbon source which are methane and ethylene mixture. The reason we used a three stage furnace is to preheat the carbon source at higher temperatures and to synthesize CNTs at lower temperatures. This method can be effective to grow SWNTs at lower temperature. Furnace temperature, methane flow, productivity of CNTs and the diameter distributions of CNTs were considered in the process of CNTs synthesis. The lowest synthesis temperature of CNTs grown from ferritin nanoparticles was 700°C. In the future, it is possible to apply this method to grow CNTs on electronic devices at the lower temperature.

Keywords: carbon nanotubes, nanoparticles, CVD, synthesis temperature.

1. Introduction

Carbon nanotubes (CNTs) were discovered by Iijima in 1991 [1], carbon nanotubes have been intensively studied in chemistry, physics, and materials science. Numerous methods to grow CNTs have been developed, including arc discharge, chemical vapor deposition, pulsed laser ablation and so on [2-4]. Chemical vapor depositions (CVD) of SWNTs has been proved to be a classic method to produce SWNTs. Compared to the arc discharge and laser ablation methods, CVD could offer more control over the growth temperature, catalyst composition, feeding gas, and other parameters [5-7].

There were already a few reports on carbon nanotube growth utilizing ferritin as a catalyst. Zhang et al. dispersed iron oxide nanoparticles produced from apoferritin on a mesoporous alumina support and synthesized single-walled carbon nanotubes (SWNTs) at 900°C [8]. Diameter-controlled growth of MWNTs has been achieved by CVD with ferritin by Daiyu et al. [9].

In this paper, we report on the single-wall carbon nanotube synthesis on a silicon oxide substrate using ferritin as a catalyst by chemical vapor deposition process in a furnace with three different heating regions at a temperature as low as 700°C.

2. Experimental

A CVD set-up equipped with a 1 inch quartz tube furnace was used. In the CVD, three heating zones in the furnace can be individually controlled to heat up. The catalyst we used was ferritin consisting of a protein shell and iron particles [10]. Concentration of the ferritin solution was controlled to 0.5 g/L by deionized water dilution. Silicon wafers with 500 nm thermal oxide layer were used as substrates. Then, the substrates were placed on a flat quartz board and inserted into the three positions of a 1 inch diameter quartz tube into the CVD furnace, as show in Figure 1.1(a). The furnace was heated up to 950°C, 850°C, and 750°C in 50 minutes. Growing nanotubes on the substrate took place for 10 minutes under combined flows of 500 sccm of H₂, 20 sccm of C₂H₄ and 62-1000 sccm of CH₄. The region at 950°C was a preheating zone, 850°C was a transition zone and 750°C was a growth zone, as show in Figure 1.1(b).

The diameters of the ferritins, nanoparticles, and nanotubes were mainly determined with an Atomic Force Microscope (AFM) in the tapping mode. High-resolution transmission electron microscopy (HR-TEM; 2100F, JEOL) and scanning electron microscopy (SEM; ERA 8800, Elionix) were used to characterize the carbon nanotubes.

3. Results and Discussion

An AFM image of ferritin on a silicon substrate is shown in Figure 1.2. The diameter of ferritin is about 12 nm. It can be seen in the image that the ferritin molecules are uniformly distributed on the substrate. After nanotube growth, we scanned 20 different areas (unit area 10 μm × 10 μm) on the substrate by AFM and recorded the counts, lengths and diameters of nanotubes. We defined the productivity of nanotubes as the total length of nanotubes per unit area. The counts of nanotubes synthesized at 950°C and 850°C, under the flow rate of 500 sccm of H2, 20 sccm of C2H4 and 62-1000 sccm of CH4, are as listed in Table 1.1. The productivity of SWNTs per 100 μm² at 950°C and 850°C are shown in Figure 1.3. The optimal productivity of SWNTs was obtained when the 500 sccm of CH4 at 950°C and 250 sccm of CH4 at 850°C were conducted, respectively. Figure 1.4 shows the diameter distribution of SWNTs grown at 950°C and 850°C. The SEM images of the diameters of SWNTs were 3.2 nm and 3.8 nm at 950°C and 850°C, respectively, as shown in Figure 1.5.

Few SWNTs were grown at 750°C, which was controlled by the catalyst of ferritin only when the flow rate with CH4 of 250 sccm, C2H4 of 20 sccm and H2 of 500 sccm. The diameters of SWNTs were 0.85~3.3 nm and the length was about 1~5 μm, as shown in Figure 1.6. The productivity of SWNTs at 700°C was less than that at 750°C only when the flow rate was controlled with CH4 of 125 sccm, C2H4 of 20 sccm and H2 of 500 sccm. The diameters of SWNTs were 0.9~2.2 nm and the length about 2~5μm, as shown in Figure 1.7.

4. Conclusions

In summary, experimental results revealed that the reaction gases showed an optimal flow rate at different growth temperatures. The flow rate of methane is important to synthesize SWNTs at low temperature. A higher flow rate of methane would reduce the catalytic activity by the great amount of carbon decomposition at the suitable growth temperature. The flow rate of methane can be reduced by decreasing the growth temperature. We couldn’t synthesize SWNTs from ferritin on the substrate at 675°C. It is possible that the catalyst and carbon source are hard to react at this temperature. In our study, the
lowest temperature at which a growth of SWNTs by the catalyst of ferritin was observed was 700°C and the mean diameter of SWNTs was 1~4 nm.
