A variety of papillary lesions affect the oral mucosa. In this section, we will focus on papillary lesions caused by various subtypes of human papillomavirus (HPV). HPV is a DNA virus that infects epithelial cells of the skin and mucosa resulting in solitary or multifocal epithelial lesions. Differentiating these lesions can be clinically difficult; in the following pages we present subtle clinical clues that can help. In some cases, histologic examination and HPV subtyping is needed to differentiate the lesions.

2.1 Verruca Vulgaris

Also known as the common skin wart. It is uncommon in mouth, but verruca vulgaris is very common on the skin, often occurring on the hands in children.

Clinical Appearance  Papillary, exophytic, white growth. Vary in size, most often a few millimeters to 1 cm. Multiple lesions are not uncommon. Asymptomatic.

Etiology  Viral – human papillomavirus (HPV), often as the result of auto-inoculation from cutaneous warts of the fingers. The associated HPV subtypes are that of the “low-risk” subtypes (HPV-2, HPV-4, and HPV-40).

Location  Anywhere, common in the anterior aspects of the oral cavity (i.e., anterior gingiva, lips, anterior tongue) – site that are easily auto-inoculated by putting infected fingers in mouth.

Differential Diagnosis  Squamous papilloma, condyloma acuminatum, oral lesions of Heck disease, giant cell fibroma, and verruciform xanthoma.

Fig. 2.1 Verruca vulagris. White warty lesion of the fingertip and nail bed of a child
2.2 Squamous Papilloma

**Clinical Appearance**  Papillary, exophytic, white growth, often on a stalk. Vary in size, most often a few millimeters to 1 cm. Most often lesions are solitary and asymptomatic.

**Etiology**  Viral – human papillomavirus (HPV), most commonly types 6 and 11.

**Location**  Anywhere in the oral cavity.

---

**Fig. 2.2**  Verruca vulgaris. White, raised, papillary growth of the ventral tongue

**Treatment**  Conservative surgical excision, recurrence unlikely but possible. Some lesions resolve spontaneously over time.

**Clinical Clue**  Examining the patient’s hands for cutaneous lesion may aid in diagnosis.
2 Papillary Lesions

Differential Diagnosis  Verruca vulgaris, condyloma acuminatum, oral lesions of Heck disease, giant cell fibroma, and verruciform xanthoma.

Treatment  Conservative surgical excision, recurrence unlikely.
2.3 Condyloma Accuminatum

Also known as a genital wart. It is uncommon in children. The presence of oral condylomas in children can be an indicator of sexual abuse.

Clinical Appearance  Exophytic, white growth with blunted papillary projections and a broad base, often described as having a cauliflower-like appearance. Vary in size, most often about 1 cm, which is larger than oral squamous papilloma and verruca vulgaris. Multiple lesions are common. Asymptomatic.
**Etiology** Viral – human papillomavirus (HPV), 90% of cases are attributed to HPV 6/11 “low-risk HPV” subtypes; however, co-infection with “high-risk” HPV subtypes 16/18 frequently occurs. Transmission can be the result of genital-oral contact, prenatal infection, digital inoculation, and possibly fomite transmission. In children, sexual abuse is the most common mode of transmission.

*Fig. 2.7* Condyloma acuminatum. Multiple pink-white raised growths with short blunted surface papillations involving the lower labial mucosa. Patient is an adult

*Fig. 2.8* Condyloma acuminatum. Exophytic growth of the ventro-lateral tongue with short, white, blunted surface papillations. Patient is an adult
Fig. 2.9  Condyloma acuminatum. Multiple raised growths with short white blunted surface papillations giving the lesions an appearance that resembles a head of cauliflower. The lesions involve the lower labial and anterior buccal mucosa. Patient is an adult.

Fig. 2.10  Condyloma acuminatum. Child presenting with an exophytic growth of the lower labial mucosa. The lesion has a broad base and blunted papillations.
**Location**  Most frequently on the soft palate, labial mucosa, and lingual frenum. The soft palate is the most common site in children.

**Differential Diagnosis**  Verruca vulgaris, squamous papilloma, condyloma acuminateum, oral lesions of Heck disease, giant cell fibroma, and verruciform xanthoma.

**Treatment**  Conservative surgical excision, recurrence unlikely but possible. Some lesions resolve spontaneously over time. Excisional biopsy might be required to establish the diagnosis.

---

**Clinical Clue**  Lesions are often multiple and appear to have a short blunt papillae resulting in a so-called cauliflower-like appearance, are typically larger that squamous papilloma and verruca vulgaris, often occur in clusters, and have a broad base rather than a stalk.

---

### 2.4 Heck Disease (Focal Epithelial Hyperplasia)

**Clinical Appearance**  Broad based, slightly elevated, papillary, or smooth-surfaced papules. Range from the color of normal mucosa to white. Individual lesions are 0.3–1.0 cm and well demarcated, but they frequently cluster together producing a cobblestone appearance. Heck’s disease was originally described in North American Natives but is now known to exist in numerous race and ethnic groups. Primarily occurs in children and is highly contagious. Asymptomatic.

**Location**  Anywhere in the oral cavity – sites of greatest involvement include the labial, buccal, and lingual mucosa.

**Differential Diagnosis**  Verruca vulgaris, squamous papillomas, condyloma acuminateum, neurofibromas, and mucosal neuromas.

**Treatment**  Unnecessary. Lesions resolve spontaneously over time (months to years). Conservative surgical excision can be performed if visible lesions are of esthetic concern. Excisional biopsy might be required to establish the diagnosis.
Fig. 2.11 (a–d) Heck disease. Four-year-old male child from South America with multiple, pink, flat to slightly papillary growths of the anterior dorsal tongue, upper and lower lip mucosa, and buccal mucosa. Child also noted to have caries of maxillary lateral and central incisors.
