Differential diagnoses of pulmonary adenocarcinomas. Figures 7C-53A–7C-53C. Hyperplastic goblet cells. Figure 7C-53D. Histiocyte distended with phagocytized mucin (muciphage). Figure 7C-53E. Lipophage. Figures 7C-53F–7C-53H. Reactive, hypertrophic type II pneumocytes. All these benign cells constitute important diagnostic pitfalls as they can be misinterpreted as adenocarcinoma. Figures 7C-54A and 7C-54B. Alveolar histiocytes in mucus streaks in sputum resemble well differentiated adenocarcinoma cells. Figures 7C-55A–7C-55C. Compare these adenocarcinoma cells in sputum to histiocytes of Figures 7C-54A–7C-54B. Figures 7C-56A and 7C-56B. Mucinous BAC cells in bronchial washings strongly resembling alveolar histiocytes. Figures 7C-57A and 7C-57B. BAC cells in BAL difficult to identify from histiocytes. Figures 7C-58A and 7C-58B. Degenerating columnar cells with vacuolated cytoplasm may be interpreted as adenocarcinoma. Figures 7C-59A and 7C-59B. Pulmonary adenocarcinoma versus hyperplasia of respiratory epithelium. Tissue fragments of hyperplastic respiratory epithelium bearing resemblance to adenocarcinoma cells. Presence of cilia (arrows) favors the benign nature. Figure 7C-60. Tissue fragment of hyperplastic respiratory epithelium.
