Target Station Optimization for the High-Brilliance Neutron Source HBS

Simulation Studies Based on the Monte Carlo Method

Series: Springer Theses

- Nominated as an outstanding Ph.D. thesis by the RWTH Aachen, Aachen, Germany
- Provides easy access to the topic, covering all the basic theory required to understand the physical processes relevant to neutron sources
- Derives qualitative statements that apply generally to the engineering design of neutron sources
- Includes numerous diagrams and tables of parameter dependencies that help to quantitatively estimate the achievable performance of a real-world plant

In the present work, the target station of the accelerator-driven neutron source HBS is optimized in comprehensive parameter studies using the Monte-Carlo method. The dependence of the most important performance characteristics of such a system on the external parameters is investigated neglecting technical and mechanical limitations. In this way, qualitative and quantitative statements for all possible configurations and envisaged applications can be derived and should be considered in the detailed planning of such facilities. For this purpose, different scenarios are considered that place completely different requirements on the design of the target station. The central statements derived in this thesis can be transferred to any framework conditions, such as different accelerator energies, so that these results can be used in the development of other neutron sources, which together with the HBS form a European network and provide a prosperous community in neutron science.
