André Unterberger

# Pseudodifferential Analysis, Automorphic Distributions in the Plane and Modular Forms

Series: Pseudo-Differential Operators

- Presents pseudodifferential analysis tailored to the needs of number theorists
- Besides containing novel features of the Weil calculus, it may constitute an approach to non-holomorphic modular form theory, suitable for analysts
- Gives hints to possible generalizations of the construction of new classes of automorphic functions
- Explains how and why pseudodifferential analysis should be developed in the adelic setting
- Series of Kloosterman sums, some of which are of a novel kind, play a major

Pseudodifferential analysis, introduced in this book in a way adapted to the needs of number theorists, relates automorphic function theory in the hyperbolic half-plane to automorphic distribution theory in the plane. Spectral-theoretic questions are discussed in one or the other environment: in the latter one, the problem of decomposing automorphic functions in according to the spectral decomposition of the modular Laplacian gives way to the simpler one of decomposing automorphic distributions in  $\mathbb{R}^2$  into homogeneous components. The Poincaré summation process, which consists in building automorphic distributions as series of  $g$ -transforms, for  $g \in \mathrm{SL}(2; \mathbb{Z})$ , of some initial function, say in  $S(\mathbb{R}^2)$ , is analyzed in detail. On , a large class of new automorphic functions or measures is built in the same way: one of its features lies in an interpretation, as a spectral density, of the restriction of the zeta function to any line within the critical strip. The book is addressed to a wide audience of advanced graduate students and researchers working in analytic number theory or pseudo-differential analysis.
